DURING A COMPETITION, I TOLD THE PROGRAMMERS ON OUR TEAM THAT $e^\pi - \pi$ WAS A STANDARD TEST OF FLOATING-POINT HANDLERS -- IT WOULD COME OUT TO 20 UNLESS THEY HAD ROUNDING ERRORS.

Kantorovich

The Newton-Kantorovich theorem gives sufficient conditions for the convergence of Newton's method.

Theorem: Let X and Y be Banach spaces and $F : D \subset X \rightarrow Y$. Suppose that on an open convex set $D_0 \subset D$, F is Frechet differentiable and

$$\|F'(x) - F'(y)\| \leq K\|x - y\|, x, y \in D_0.$$

For some $x_0 \in D_0$, assume that $\Gamma_0 = [F'(x_0)]^{-1}$ is defined on all of Y and that $h := \beta K \eta \leq \frac{1}{2}$ where $\|\Gamma_0\| \leq \beta$ and $\|\Gamma_0 F x_0\| \leq \eta$. Set

$$t^* = \frac{1}{\beta K} (1 - \sqrt{1 - 2h}), \quad t^{**} = \frac{1}{\beta K} (1 + \sqrt{1 - 2h})$$

and suppose that $S := \{x \mid \|x - x_0\| \leq t^*\} \subset D_0$. Then the Newton iterates $x_{k+1} := x_k - [F'(x_k)]^{-1} F x_k$, $k = 0, 1, \dots$, are well defined, lie in S and converge to a solution x^* of $F x = 0$ which is unique in $D_0 \cap \{x \mid \|x_0 - x\| < t^{**}\}$. Moreover, if $h < \frac{1}{2}$ the order of convergence is quadratic.

- ▶ Faster real computation
- ▶ Numerical integration
- ▶ Picard method

Integration

Experiment building a
library

Faster real
computation

Numerical integration
Picard method

Experiment building a library

Request for input

Three libraries: `stdlib`, `corn`, `ssr`.

`ssr`: solves many problems, but discrete

`corn`: computational continuous structures, needs updating

Experiment using type classes.

To be integrated with canonical structures → unification hints?

Dyadics

Improve efficiency of the reals.

The current implementation (O'Connor) is fast, but can be improved.

Use dyadics instead of rationals, use machine integers (Krebbbers)

Code refactoring, data structures ...

Example: verified plot of a circle.

Newton-Cotes:

Approximate a function by a polynomial and integrate this.

Definition

Let x_1, \dots, x_n be distinct and y_1, \dots, y_n arbitrary, then a unique polynomial L of degree at most $n - 1$ exists with $L(x_k) = y_k$.

This polynomial is called the **Lagrange polynomial**.

Explicitly, $L(x) := \sum_j y_j \prod_{i,j \neq i} \frac{x-x_i}{x_j-x_i}$.

Definition L: cpoly CRasCRing :=

```
Sigma (map (fun p => let '((x, y), rest) := p in
  _C_ y [*] Pi (map (fun xy' => (' (- fst xy') [+X*] One)
    [*] _C_ (' (/ (x - fst xy'))))) rest)) (separates qpoints)).
```

Theorem (Lagrange error formula)

Let f be n times differentiable. Then for all x ,

$$|f(x) - P_n(x)| \leq \frac{\prod(x-x_k)}{n!} \sup |f^{(n)}|.$$

Proof uses generalized Rolle's theorem.

This is a paradigmatic example.

Theorem (Classical Rolle's theorem)

Let f be differentiable and have two zeroes in an interval $[a, b]$. Then f' has a zero in (a, b) .

Theorem (Classical generalized Rolle's theorem)

Let f be n times differentiable and have $n + 1$ zeroes in an interval $[a, b]$. Then $f^{(n)}$ has a zero in $[a, b]$.

Is not constructive, i.e. does not compute inside Coq.

Hermite-Genocchi formula

Replace Generalized Rolle by Hermite-Genocchi.

Let R be a field and $f : R \rightarrow R$. The interpolation polynomial in the Newton form is a linear combination of Newton basis polynomials

$$N(x) := \sum_{j=0}^k a_j n_j(x)$$

with the Newton basis polynomials defined as

$$n_j(x) := \prod_{i=0}^{j-1} (x - x_i)$$

and the coefficients defined as $a_j := f[x_0, \dots, x_j]$, where $f[x_0, \dots, x_j]$ is the notation for [divided differences](#):

Hermite-Genocchi formula

divided differences defined recursively by:

$$f[a] = f(a)$$

$$f[a, b] = f(a) - f(b)/a - b$$

$$f[a, b, c] = f[a, c] - f[b, c]/a - b$$

and in general, $f[a : b : l] := f[a : l] - f[b : l]/a - b$.

Integration

Corollary,

$$f(x) - P_n f(x) = \prod_{i=1}^n (x - x_i) \int \int_{n-1} f^{(n-1)}(u_1 a_1 + \dots + u_n a_n) d\vec{u}$$

Replace differentiation by integration

Simpson's rule

Corollary (Simpson's rule)

If $|f^{(4)}| \leq M$, then

$$\left| \int_a^b f(x) dx - \frac{b-a}{6} \left[f(a) + 4f\left(\frac{a+b}{2}\right) + f(b) \right] \right| \leq \frac{(b-a)^5}{2880} M.$$

The right hand side is the integral of the Lagrange polynomial P_3 at a , $\frac{a+b}{2}$, b . For the error we adopt the classical proof, but replace the use of Rolle's theorem and the Mean Value Theorem by the Hermite-Genocchi formula.

Simpson's rule

Corollary (Simpson's rule)

If $|f^{(4)}| \leq M$, then

$$\left| \int_a^b f(x) dx - \frac{b-a}{6} \left[f(a) + 4f\left(\frac{a+b}{2}\right) + f(b) \right] \right| \leq \frac{(b-a)^5}{2880} M.$$

The right hand side is the integral of the Lagrange polynomial P_3 at $a, \frac{a+b}{2}, b$. For the error we adopt the classical proof, but replace the use of Rolle's theorem and the Mean Value Theorem by the Hermite-Genocchi formula. Define $F(t) := f\left(\frac{a+b}{2} + \frac{b-a}{2}t\right)$. This reduces the problem to showing that $\left| \int_{-1}^1 F(\tau) d\tau - \frac{1}{3}(F(-1) + 4F(0) + F(1)) \right| \leq N/90$, where $|F^{(4)}| \leq N$

Integration

Experiment building a
library

Faster real
computation

Numerical integration
Picard method

Simpson's rule

Define

$$G(t) = \int_{-t}^t F(\tau) d\tau - \frac{t}{3}(F(-t) + 4F(0) + F(t))$$

We need to prove that $90G(1) \leq \|F^{(4)}\|$.

Simpson's rule

Define

$$G(t) = \int_{-t}^t F(\tau) d\tau - \frac{t}{3}(F(-t) + 4F(0) + F(t))$$

We need to prove that $90G(1) \leq \|F^{(4)}\|$. To do so, define $H(t) := G(t) - t^5G(1)$. Then

$$H(0) = H(1) = H'(0) = H''(0) = 0.$$

Simpson's rule

Define

$$G(t) = \int_{-t}^t F(\tau) d\tau - \frac{t}{3}(F(-t) + 4F(0) + F(t))$$

We need to prove that $90G(1) \leq \|F^{(4)}\|$. To do so, define $H(t) := G(t) - t^5G(1)$. Then

$$H(0) = H(1) = H'(0) = H''(0) = 0.$$

Hence, $H[0, 0, 0, 1] = -(H[0, 0, 0] - H[0, 0, 1]) = 0 + (-H[0, 0] + H[0, 1]) = 0$.

Moreover, $H^{(3)}(t) = -\frac{t}{3}(F^{(3)}(t) - F^{(3)}(-t)) - 60t^2G(1) = -\frac{t}{3}(\int_{-t}^t F^{(4)}) - 60t^2G(1)$.

Simpson's rule

This shows that

$$\begin{aligned}0 = H[0, 0, 0, 1] &= \int_0^1 H^{(3)} \\&= \int_0^1 -\frac{t}{3} \left(\int_{-t}^t F^{(4)} \right) - 60t^2 G(1) \\&\geq \int_0^1 -\frac{t}{3} 2tN - 60t^2 G(1) \\&= -\frac{2}{3} (N + 90G(1)) \int_0^1 t^2 \\&= -\frac{2}{3} (N + 90G(1)) \frac{1}{3}.\end{aligned}$$

Integration

Experiment building a
library

Faster real
computation

Numerical integration
Picard method

Simpson's rule

This shows that

$$\begin{aligned}0 = H[0, 0, 0, 1] &= \int_0^1 H^{(3)} \\ &= \int_0^1 -\frac{t}{3} \left(\int_{-t}^t F^{(4)} \right) - 60t^2 G(1) \\ &\geq \int_0^1 -\frac{t}{3} 2tN - 60t^2 G(1) \\ &= -\frac{2}{3} (N + 90G(1)) \int_0^1 t^2 \\ &= -\frac{2}{3} (N + 90G(1)) \frac{1}{3}.\end{aligned}$$

Hence, $N \geq -90G(1)$. Similarly, $0 \leq -\frac{2}{9}(-N + 90G(1))$.

Consequently, $90G(1) \leq N$. We conclude that

$|90G(1)| \leq N$.

Differentiation over general fields [Bertrand, Glöckner, Neeb]

The proofs are 'algebraic' in nature and in this way become often simpler and more transparent even than the usual proofs in \mathbb{R}^n because we avoid the repeated use of the Mean Value Theorem (or of the Fundamental Theorem) which are no longer needed once they are incorporated in [the definition of the derivative by a difference quotient].

Integration

Experiment building a
libraryFaster real
computationNumerical integration
Picard method

Picard existence theorem

Given the initial value problem:

$$y'(t) = f(t, y(t)), \quad y(t_0) = y_0, \quad t \in [t_0 - \alpha, t_0 + \alpha]$$

Suppose f is Lipschitz continuous in y and continuous in t .
Then, for some $\varepsilon > 0$, there exists a unique solution $y(t)$ to
the initial value problem within the range $[t_0 - \varepsilon, t_0 + \varepsilon]$.

Proof of Picard method

Picard iteration:

Set $\varphi_0(t) = y_0$ and

$$\varphi_i(t) = y_0 + \int_{t_0}^t f(s, \varphi_{i-1}(s)) ds.$$

The sequence of Picard iterates φ_i is convergent and that the limit is a solution to the problem. The width of the interval where the local solution is defined is entirely determined by the Lipschitz constant.

Picard method

Consider a concrete C^∞ function, say $\lambda x. \sin(\sin x)$

To compute the integral we need an upper bound on the derivative.

Cruz-Filipe's tactic automatically finds a provable derivative.

The sup function (O'Connor/S) computes bound.

Finally, we apply Simpson's rule.
